# 1 Query Statistics

In this section, we show both query trees and MySQL execution plan for the first non-optimized and final optimized version of each query. Moreover, we provide parallel query processing reports for each query. This illustrates the optimization of the query statements that might include schema, query rewriting, semantic and statistical heuristics.

**Note that,** the cost estimates in MySQL execution plan can be inaccurate, due to the following:

- 1. The unit of the cost is an abstract number that not necessarily relate to the real execution. It's just used as a heuristic to order certain operations in the query execution.
- 2. MySQL estimator considers equal costs for both CPU and IO operations, which isn't valid, due to modern processors' speeds.
- 3. MySQL estimator doesn't consider database indexes.

# 1.2 Query 2

#### 1.2.1 Execution Plan Before Optimization

**Note that,** due to the huge execution time of the query before adding the indexes, we can't extract the actual non-optimized visual execution plan. Therefore, we included the visual execution plan after *index optimization*.

# 2 Optimization Details

In this section, we show the optimization details done through this work. We discuss the statistics of the new database and the schema changes. Moreover, other optimization techniques related to query, indexes and memory are discussed, as well.

#### 2.1 New Database Statistics

In this subsection, we show the new database statistics after optimization. The record count is extracted from the database filled with 100000 records per table. Other filling sizes are considered through the analysis like 10000 and 1000000.

Table Name	Row Count	Main Key	Indexes	FK
Disaster	100000	YES	4	2
Causes	100000	YES	1	1
Precautions	100000	YES	1	1
Incident	100000	YES	4	3
Descriptions	100000	YES	1	1
Casualty	25000	YES	1	0
Government_Representative	25000	YES	1	0
Govn_Rep_Credentials	25000	YES	1	1
Citizen	25000	YES	1	0
${\it Citizen\_Credentials}$	25000	YES	1	1
Criminal	25000	YES	1	0
Report	100000	YES	5	4
Report_Content	100000	YES	1	1
Casualty_Incident	100000	YES (Composite)	3	2

Table Name	Identity Column	Max Row Size (Bytes)
Disaster	YES	52
Causes	YES	65538
Precautions	YES	65538
Incident	YES	120
Descriptions	YES	65538
Casualty	YES	105
Government_Representative	YES	116
Govn_Rep_Credentials	YES	103
Citizen	YES	116
Citizen_Credentials	YES	103
Criminal	YES	106
Report	YES	23
Report_Content	YES	65538
Casualty_Incident	NO	6

### 2.2 Schema Optimization

The following database schema shows the optimizations over the old schema. The schema optimizations can be summarized as follows:

- 1. **Denormalization** of *Person* table with all persons types. This is mainly because no duplicates between persons types. For example, no person can be a casualty and a criminal at the same time. So, in order to avoid redundant joins, the *Person* relation is merged into the four child relations.
- 2. **Normalization** (Vertical Partitioning) of variable-size data. The access of fixed-size records is faster than that of variable-size data, as the DBMS don't require to pre-calculate the record size. That's why, the variable-size data like text, usernames and passwords are separated into separate relations. One more reason for doing so is that the data in these fields aren't accessed frequently, so they better be separate from other frequently-accessed data.

- 3. **Minimization** of the data types based on semantic and statistical *heuristics*. The data types of different fields are reduced to the minimum possible size, in order to ease their read and write to the disk. For example, all *primary keys* are reduced to MEDIUMINT, because the table size is at most 1000000. Moreover, Some fields that are just limited to range from 1 to 10 are reduced to 4 bits instead of INT.
- 4. **Conversion** of variable-size data to fixed-size data. As the fixed-size record are faster to access and transfer, so each *VarChar* is converted into *Char*. This, however, can increase the storage space, as *Char* allocates the target bytes whatever they are all used or not.
- 5. Usage of NOT NULL, whenever possible. If the field isn't marked as NOT NULL, it allocates extra bits to check whether the field is *NULL* or not.

# 3 Validation Details

# 3.1 Time and Space Analysis

In this subsection, we evaluate both time and space improvements of each optimization on each query. We consider both before and after *disk cache*. Moreover, the space improvement is considering the **total size** of the transferred tables between memory and disk. Execution time is measured in *seconds*.

Query 1	Before Cache			After Cache		
Query 1	Time	Time %	Space %	Time	Time %	Space %
Initial Query	17.61	-	-	1.15	-	-
Index Opt.	-	-	-	-	-	-
Query Opt.	10.87	38%	25%	0.39	66%	25%
Schema Opt.	8.41	22.6%	99.8%	0.33	15.4%	99.8%
Memory Opt.	7.89	6%	-	0.3	9%	-
Query 2	Before Cache			After Cache		
Query 2	Time	Time %	Space %	Time	Time %	Space %
Initial Query	1535	-	-	1463	-	-
Index Opt.	7.83	99.4%	-	0.62	99.9%	-
Query Opt.	1.71	78%	-	0.17	72.5%	-
Schema Opt.	1.38	19.2%	99.8%	0.15	11.8%	99.8%
Memory Opt.	1.29	6.5%	-	0.13	13.3%	-

Query 3	Before Cache			After Cache		
Query 5	Time	Time %	Space %	Time	Time %	Space %
Initial Query	0.36	-	-	0.07	-	-
Index Opt.	0.23	36%	-	0.01	85.7%	-
Query Opt.	0.19	17%	-	0.01	0%	-
Schema Opt.	0.14	26%	99.8%	0	100%	99.8%
Memory Opt.	0.12	14%	-	0	0%	-
Ouery 4	Before Cache			After Cache		
Query 4	Time	Time %	Space %	Time	Time %	Space %
Initial Query	10.41	-	-	0.27	-	-
Index Opt.	-	-	-	-	-	-
Query Opt.	-	-	-	-	-	-
Schema Opt.	6.96	33.1%	99.8%	0.16	40.7%	99.8%
Memory Opt.	6.57	5.6%	-	0.13	18.75%	-

Query 5	Before Cache			After Cache		
Query 5	Time	Time %	Space %	Time	Time %	Space %
Initial Query	14.96	-	-	0.44	-	-
Index Opt.	-	-	-	-	-	-
Query Opt.	4.82	67.7%	-	0.24	45%	-
Schema Opt.	3.37	30%	99.85%	0.2	16.67%	99.85%
Memory Opt.	2.34	30%	-	0.19	5%	-

#### 3.2 Database Size Effect

The following plots show the effect of increasing database sizes on the execution time of our 5 queries. We consider both before and after  $disk\ cache$ .

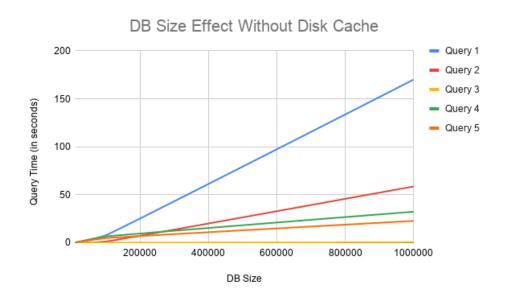

Figure 20: Database Size Effect Without OS (Disk) Cache.

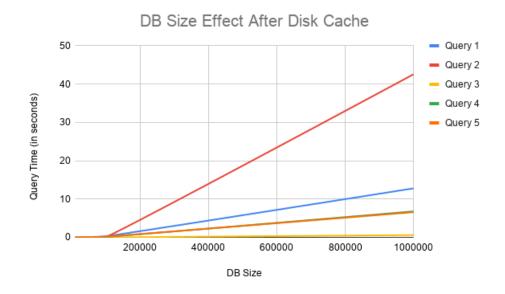

Figure 21: Database Size Effect After OS (Disk) Cache.

# 3.3 Optimized SQL vs. NoSQL

The following plot shows the different in execution time of each query between optimized SQL and NoSQL. The comparison is done on a database with 100,000 records per table.

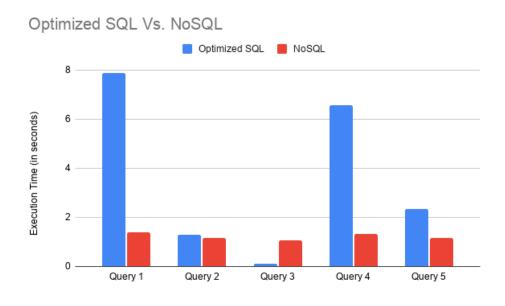

Figure 22: Comparison between optimized SQL and NoSQL on 100,000 records per table.

#### 3.4 Hardware Effect

### 4 Final Remarks

In this work, we have discussed various database optimization techniques and showed how the query execution time can be affected for both SQL and NoSQL databases. The final remarks can be summarized as follows:

- $\bullet$  With good optimization, SQL databases can achieve a comparable performance with NoSQL databases.
- MySQL is a very versatile *DBMS* that can adapt to multiple optimization operations, enabling the user to increase queries execution speed.
- MongoDB can be the perfect choice for a NoSQL DBMS, as it's easy to use and deploy on very large systems.
- For some operations, *index optimization* can provide a huge performance improvement, if it's done right on specific fields in the database.
- It's a good practice to extract *semantic* and *statistical* heuristics based on your database. This can provide the developer with good insights on how to optimize queries and eliminate redundant operations.
- Try to keep the record size in frequently-accessed tables *fixed*, as it's much faster to access fixed-size records. Moreover, it's better to partition the infrequent variable-size fields into separate tables.
